## Five Strategies to Reduce DPF Downtime

### 1. Match the engine size to its intended application.

Don't spec' a big-block engine to run stop-and-go all day with short runs on the highway. Choose a smaller engine with a higher power-to-displacement ratio that will generate more exhaust heat and allow more passive regeneration and increase intervals between parked regenerations.

### 2. Observe the regen cycle frequency

Increasingly frequent active regens or parked regen requests could indicate the filter is becoming severely plugged. Onboard diagnostic systems are more sophisticated today and can alert you to the need for service, but older trucks can still be hit or miss. There is no harm in pulling the Diesel Particulate Filter for cleaning earlier in its life rather than later, and scheduled maintenance is always less expensive than emergency service.

### 3. Consider performing a parked regen at the beginning or end of a work shift

Vehicles in light-duty, highidle, or stop-and-go service can avoid disruptions to the workday by performing a scheduled regen rather than having to park for up to an hour during the shift.

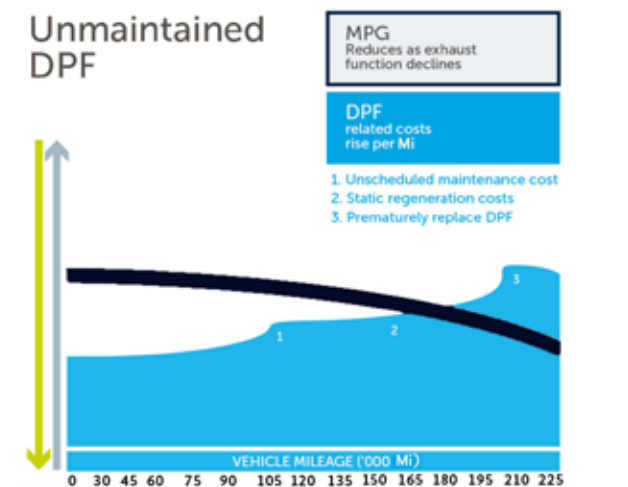

### 4. Perform regular and documented fluid level checks

An internal oil or coolant leak will no longer change the color of the exhaust because of the Diesel Particulate Filter. Such contamination increases the risk of plugging the Diesel Oxidation Catalyst, which will increase backpressure. After ineffective active or even passive regenerations, the system monitors will trigger fault codes and activate dash lamps to recommend inspection.

### 5. Watch fault codes

The days of performing preventive maintenance without a computer are over. Respond to fault codes immediately and be proactive. A parked regen is a last resort, not a first warning.
